1. Sensor Overview

1.1 General Description

GC2155 is a high quality 2Mega CMOS image sensor, for mobile phone camera applications and digital camera products. GC2155 incorporates a 1616V x 1232H active pixel array, on-chip 10-bit ADC, and image signal processor.

According to different light conditions , The on-chip ISP provides a very smooth AE (Auto Exposure) and accurate AWB (Auto White Balance) control .Besides , interpolation, de-noise, and color correction, gamma correction are supported, which can revert the real scene better. The sensor also provides various data formats, such as Bayer RGB, RGB565, YCbCr 4:2:2. All sensor parameters and features are controlled through a standard 2-wire serial interface.

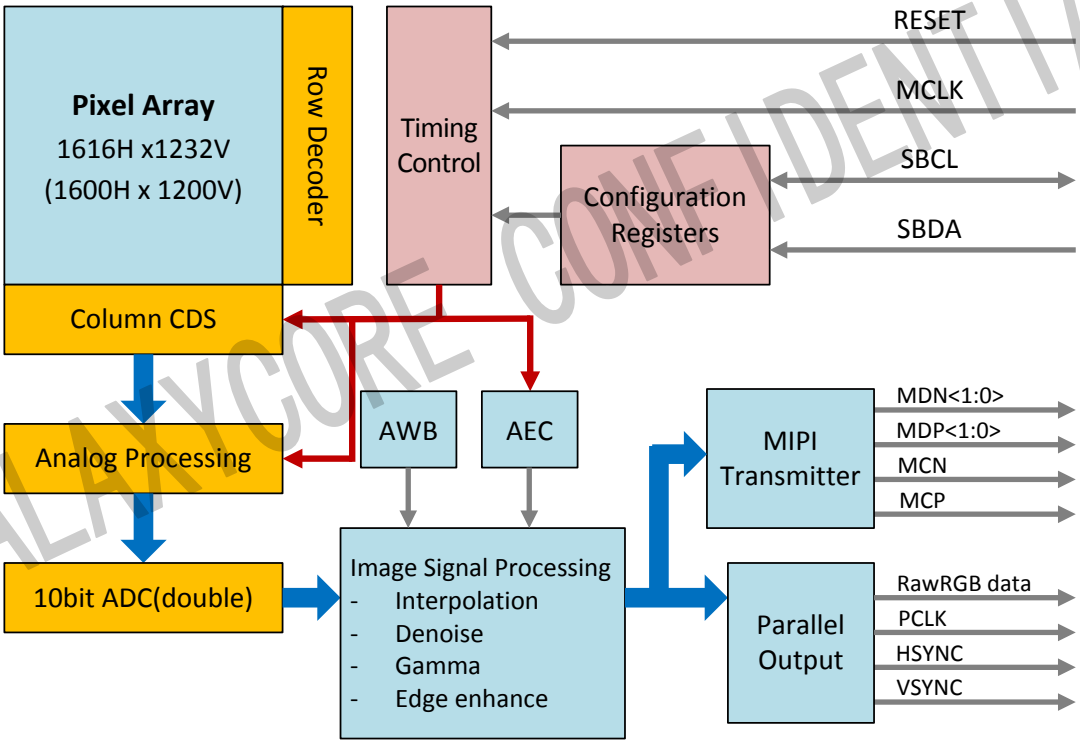
2. Block Diagram



GC2155 has an active image array of 1616 x 1232 pixels. The active pixels are read out progressively through column/row driver circuits. In order to reduce fixed pattern noise, CDS circuits are adopted. The analog signal is transferred to digital signal by 10 bit A/D converter. The digital signals are processed in the ISP Block, including Bayer interpolation, de-noise, and color correction, gamma correction, and data format conversion and so on. Users can easily control these functions via two-wire serial interface bus.

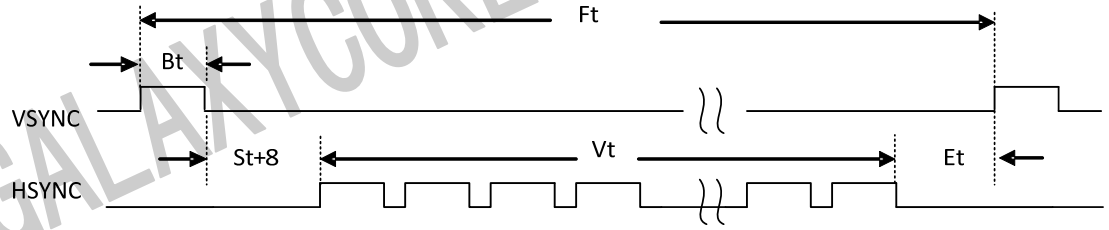
6. Applications

6.1 Timing

6.1.1 Parallel

Supposed VSYNC is LOW active and HSYNC is HIGH active, and output format is YCbCr/RGB565, then the timing of VSYNC and HSYNC is following:



Ft =VB+ Vt +8 (unit is row_time)

VB = Bt + St + Et, Vblank/Dummy line, setting by register P0:0x07 and P0:0x08.

- Ft -> Frame time, one frame time.
- Bt -> Blank time, VSYNC no active time.

- St -> Start time, setting by register P0:0x13
- Et -> End time, setting by register P0:0x14
- Vt -> valid line time. UXGA is 1200, Vt=win_height-8, win_height is setting by register P0:0x0d and P0:0x0e(1232).

When exp_time <= win_height+VB, Bt=VB-St-Et. Frame rate is controlled by window_height+VB.

When exp_time > win_height+VB, Bt=exp_time-win_height-St-Et. Frame rate is controlled by exp_time.

The following is row_time calculate:

row_time = Hb + Sh_delay + win_width + 4.

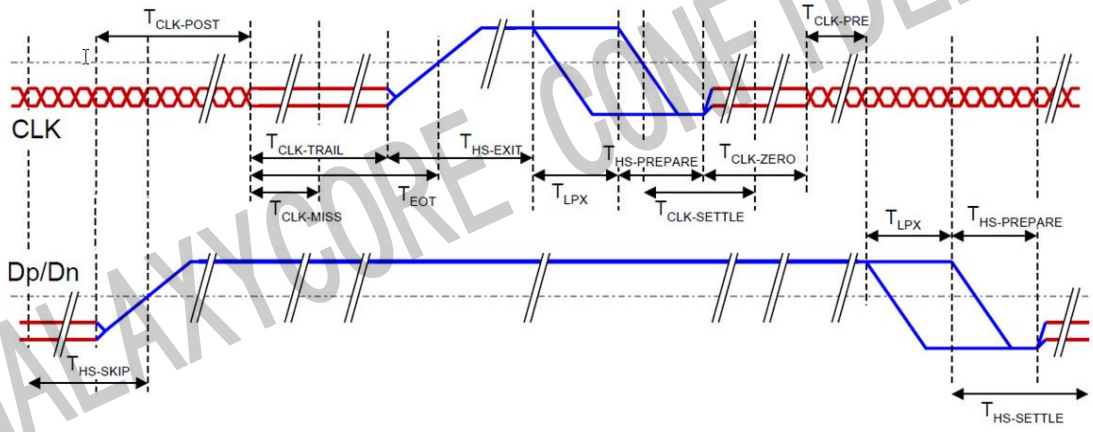
Hb –> HBlank or dummy pixel, Setting by register P0:0x05 and P0:0x06.

Sh_delay -> Setting by register P0:0x11[9:8], P0:0x12[7:0].

win_width -> Setting by register 0x0f and P0:0x10, win_width = 1600, final_output_width + 8. So for UXGA, we should set win_width as 1616.

6.1.2 MIPI

Clock lane low-power



Notice:

- Clock must be reliable during high speed transmission and mode-switching
- Clock can go to LP only if data lanes are in LP(and nothing relies on it),

- In Low –Power data lanes are conceptually asynchronous(independent of the high speed clock)

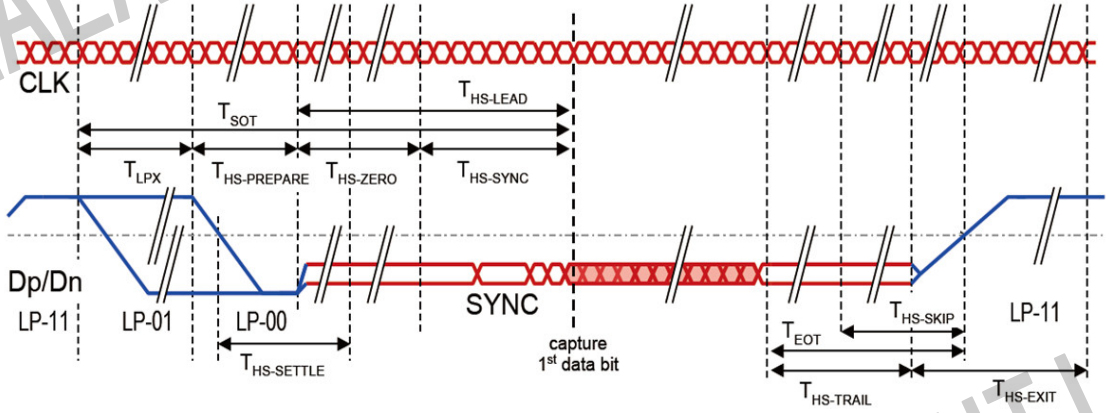
  T_{CLK_PRE}: setting by Register P3: 0x24

  T_{CLK_POST} : setting by Register P3: 0x25

  $T_{CLK\text{-}ZERO}$: setting by Register P3: 0x23

  T_{CLK_TRAIL}: setting by Register P3: 0x26

Data Burst



Notice:

- Clock Keeps running and samples data lanes(except for lanes in LPS)
- Unambiguous leader and trailer sequences required to distill real ditz,
- trailer is removed inside PHY(a few bytes)
- Time-out to ignore line values during line state transition

  T_{LPX} : setting by Register P3:0x21

  $T_{HS\text{-}PREPARE}$: setting by Register P3: 0x29

  $T_{HS\text{-}ZERO}$: setting by Register P3:0x2a

  $T_{HS\text{-}TRAIL}$: setting by Register P3:0x2b

  $T_{HS\text{-}EXIT}$: setting by Register P3: 0x27
